

Continuous Speech Emotion Recognition

Block Diagram

The diagram below shows our full method. The top boxes are normal SER steps (pre-processing, features, CNN + Bi-LSTM). The boxes tagged [Contribution] are our part. First we do window-wise emotion detection. Then we smooth weak jumps, find real change points, make stable regions, mark transitions, and print a continuous emotion timeline.

Fig. 1 Block diagram of the proposed system

About the [Contribution] boxes: window-wise detection means we slide a short window (example 2 sec with 1 sec hop) over the speech and predict emotion for each window. Smoothing fixes sudden low-confidence flips. Change points and grouping join nearby same labels into one stable region. When emotion really changes, a short Transition interval is put between the old and new emotion. The last contribution box prints the final timeline for the full speech. Mel features, CNN and Bi-LSTM are known methods and we use them

as support, not as our claim.
